PROJECT TITLE: IoT Based Paralysis Patient Healthcare Monitoring System

ABSTRACT:

Paralysis is a condition in which a person loses the ability to control muscles in certain parts of the body, often limiting movement and reducing the ability to sense pain or respond normally. Individuals affected by paralysis frequently require continuous supervision and support for their daily health and safety. While medical and technological advancements have helped improve patient care, many available solutions are costly or not easily accessible for everyday use.

This project proposes an Internet of Things (IoT) based health care monitoring system designed specifically to assist paralysis patients. The system monitors essential health parameters such as body temperature and heart rate using appropriate sensors connected to a microcontroller. The measured data is transmitted through a wireless communication module, allowing caregivers or medical professionals to monitor the patient's condition remotely.

In addition to health monitoring, the system focuses on improving patient communication. Since many paralysis patients struggle to express their needs, the proposed device enables them to convey simple messages using minimal physical movement. A small motion-based interface can be attached to a finger or integrated into wearable clothing, allowing patients to trigger predefined messages with slight movements.

The proposed solution aims to provide a simple, affordable, and practical system that supports continuous health monitoring and basic communication assistance. By combining sensing technology, wireless connectivity, and assistive communication features, the system can help improve patient care and enhance the independence and quality of life of paralysis patients.
